

Session 1

NoSQL vs SQL: History and Evolution

This work is licensed under a Creative Commons Attribution – NonCommercial – NoDerivatives 4.0 International License.

Objectives

- From the relational model to **NoSQL** models
 - Comparison of the two paradigms
 - History of the emergence of NoSQL
 - ACID and BASE properties
- **Interest** and use of NoSQL models
 - Big Data and the 4Vs
 - Distributed architecture
 - Overview of NoSQL data models

NoSQL

What does NoSQL stand for?

non relational

non SQL

not only SQL

Not your grandfather's database?

HOW TO WRITE A CV

Leverage the NoSQL boom

Relational vs NoSQL

Enterprise Computing

- Many **changes in the technology** used occurred in enterprises
Programming languages, architectures, platforms, etc.
- Stability in the way **data are stored**
Relational databases have always been used since then
- Some successful challengers do exist in small **niche markets**
Architects still choose relational databases

Software and Data

- A company uses **software** and stores **data**

Those two elements are as independent as possible

- Data often **lives longer** than softwares

New softwares must support existing data

- Data must be as **stable** as possible

Easily understandable and accessible through an API

Data

- Need to **organise data** is at the heart of computer science

While optimising storage and retrieval

- Several other important **sub-functions**

Security, protection against inconsistencies, etc.

*Storage on
mass memory*

*Data
retrieval*

Dilbert.com DilbertCartoonist@gmail.com

9-20-13 © 2013 Scott Adams, Inc. (Dist. by Universal Uclick)

I hate databases...

- Most developers do **not like databases**
 - Interact with a DBMS (DataBase Management System)
 - Learn the SQL language (Structured Query Language)
 - Links between data in the database and those in the program
- Database seen as an intrusion of an **external element**

With very poor integration with the application code

Emergence of NoSQL

- Need to store **large amounts** of data
Moving from large platforms to server clusters
- New database engines emerged under the **NoSQL** name
Cassandra, Mongo, Neo4j, Riak, etc.
- Lessening the traditional **data consistency** constraint
For performance, scalability, easy programming, etc.

Relational Model Strength

- Relational model based on a **standard model**
 - Guarantees about data consistency (constraints)
 - Efficient and persistent data storage (better than files)
 - Concurrent read/write access to data (transactions)
- **Integration** and collaboration of enterprise applications
Realised with an integration through shared database

End of Relational Model?

- Relational databases are **powerful and stable...**

Not ready to disappear in the short and medium term

- ...but they are **no longer sufficient**

Unnecessary heaviness to store certain types of data

- **Hybrid systems** combining several technologies

Concurrently, cooperatively, in a distributed way, redundantly...

History

Timeline

- 1950 Hierarchical model development (IMS)
- 1970 Appearance of relational model (*Edgar F. T. Codd*)
- 1980's Domination of the relational model
- 2000's Emergence of the NoSQL term
- 2011 Emergence of NewSQL

Hierarchical Model (1)

- Building **relationships** from parents to children

Limited to one-way relationships

- Database consists of **records** with fields

Grouped into record types

- **IMS engine** created by IBM (*Information Management System*)

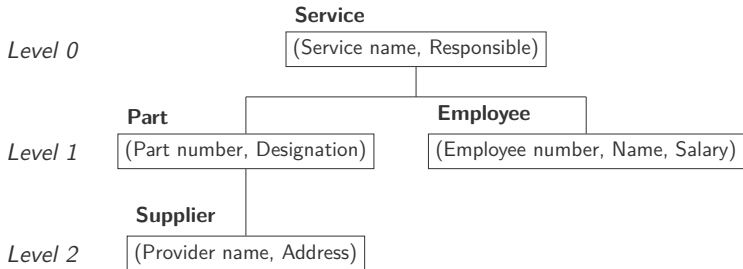

Used by NASA to manage building materials (started in 1968)

Hierarchical Model (2)

- **Hierarchy diagram** representing a service

Fields of the different record types included

Relational Model

- *“A Relational Model of Data for Large Shared Data Banks”*

*Edgar Frank “Ted” Codd, Ph.D. (1923–2003)
IBM Research, San Jose, California, USA*

- ACM A.M. **Turing Award** 1981

Theory and practice of DBMS, esp. relational databases

- Organisation of data according to a **mathematical model**

Based on set theory and relational algebra

- **Isolation of access** to data and physical implementation

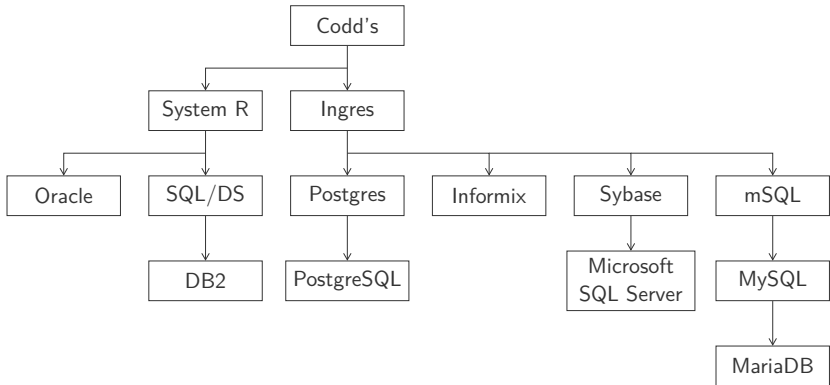

Thanks to a high-level declarative language

System R

- First implementation of SQL with the **System R** prototype
 - Developed in 1974 to experiment Codd's concepts*
- **SEQUEL** language (*Structured English Query Language*)
 - Access method: RSS (*Research Storage System*)
 - Optimising SQL processor: RDS (*Relational Data System*)
- **Pratt & Whitney** first customer of System R in 1977

Relational Model Evolution

A more complete RDBMS Genealogy has been proposed by HPI (see references).

From OLTP to OLAP

- **Online Transactional Processing (OLTP)**

Purely transactional use of data (management)

- **Online Analytical Processing (OLAP)**

Dashboard, historical and predictive analysis (statistics)

- **Limitation** of the relational model for OLAP

Aggregates, query optimisation, indexing... not enough

IT System Data

- Division of an **IT system** in two parts

A rather transactional part and a more analytical one

Relational Model Issues

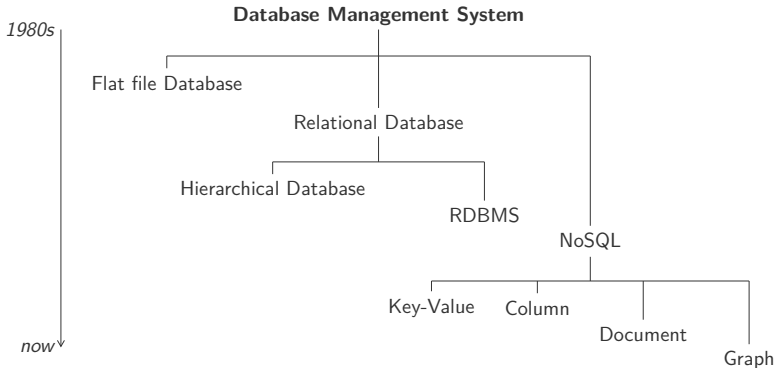

- 1 Converting information from natural representation to tables
- 2 Reconstruction of the information from tables
- 3 Need to model data (semantic) before storing it
- 4 Rigid schema forcing data from one column to have the same type
- 5 Difficult to scale (scaling)
- 6 Difficulty making joins between different systems
- 7 Several existing dialects of SQL (portability)
- 8 Some business rules difficult to express in SQL
- 9 Approximate and fuzzy searches difficult
- 10 No efficient storage and validation of complex documents

- Meetup by **Johan Oskarsson** at the Hadoop summit @ SFO
Software developer based in London for Last.fm
- **Choosing a short name**, memorable, with few Google results
#NoSQL “open-source, distributed, nonrelational databases”
- Several common **characteristics** to these databases
 - Do not use the relational model, nor SQL
 - Open source
 - Designed to be run on large clusters
 - Based on needs of web properties in the 21st century
 - No schema, possible to add field without control

DBMS Timeline

- Popular **database management systems** from 1980s to now

With the co-existence of RDBMS and NoSQL today

The NoSQL World

<http://nosql-database.org>

<http://nosql.mypopescu.com/kb/nosql>

NoSQL Interest

- **Increased productivity** during the development
 - Time saving when mapping database to the memory
 - Less code to write, debug, maintain and evolve
- Amount of data on a **large scale**
 - Fast storage of large amounts of data
 - Database distributed on server clusters

- New tendency to combine strengths of **SQL and NoSQL**
Guarantees from relational model with flexibility of NoSQL
- Often referred to as **"SQL on Steroids"** by the community
 - Based on the relational model and the SQL language
 - Scalability, flexibility and high performance from NoSQL
- **ACID properties** satisfied with horizontal scaling
The power of NoSQL when heavy OLTP transaction volumes

ACID and BASE

ACID Properties

- Set of **properties on transactions** in databases
 - Atomicity, Consistency, Isolation and Durability*
- Definition by **Reuter et Härder** in 1983
 - One transaction makes all or nothing (e.g. if power failure)
 - Database changes from one valid state to another valid state
 - Concurrent execution of transactions as if they were sequential
 - A committed transaction confirmed and stored

BASE Properties

- Managing **consistency loss** by maintaining reliability
 - Basically Available, Soft state et Eventual consistency*
- **Constraints relaxed** compared to ACID properties
 - Always a response: failure or inconsistent data possible
 - The state can change over time, even when no input
 - The system will sooner or later be consistent

CAP Theorem

- **CAP theorem** stated by Eric Brewer for distributed systems
Consistency, Availability et Partition tolerance
- Initially only calculation distribution and now **data distribution**
Clusters or grids to increase the total computing power
- Three guarantees **not satisfiable** for a distributed system
 - **Consistency** of all data on all the nodes
 - **Availability** of all data even when losing of a node
 - **Partition tolerance** to a failure not disconnecting the cluster

Shared Something vs Nothing

- **Shared-Nothing** distributed-computing architecture
 - Nodes do not share any memory or storage
 - Each update request is satisfied by a single node
 - Elimination of single-point of failure, very easy to scale
- **Shared-Something** distributed-computing architecture
 - Hybrid approach between shared-everything and shared-nothing
 - Typically shared-memory nodes and interconnection network

ACID or BASE? (1)

- **ACID** desired in a “*shared something*” environment

Pessimistic: force consistency and end of transactions

- A** everything or nothing, commit ou rollback
- C** no inconsistent data
- I** no knowledge of concurrent transactions
- D** committed transaction persistence

- **BASE** implemented in a “*shared nothing*” environment

Optimistic: accept temporary inconsistencies

- BA** guaranteed by replication
- S** consistency to be guaranteed by the application
- E** stale data possible, eventual consistency

ACID or BASE? (2)

- **Conjecture** related to the CAP theorem

Only two of the three CAP requirements can be met

- **Three situations** are possible
 - CA \sim ACID: one unique central server (with replication?)
 - CP: either “w N, r 1”, or “w 1, r N” (too slow?)
 - AP = BASE: no strong consistency guaranteed

Big Data

Big Data

- Increase of the **volume of data** handled

In particular companies and organisations related to the internet

- **Exponential increase** to petabytes of data (10^{15})

- Scientific data, medical databases
- Social networks, phone operators
- Economic and social indicators
- National territory defence agencies

- **Challenging** to manage and process this huge amount of data

Not within the reach of the traditional relational model

4Vs (1)

- Big Data characterised by an **unlimited amount** of datasets

Data very complex to collect and to store

- Data follows the **4Vs**
 - **Volume** of Pbytes, or even Ebytes, of data
 - **Velocity** for data creation, storage, analysis and visualisation
 - **Variety** of sources and types for data (image, video, sound...)
 - **Veracity** of data, obsolescence, integrity and security
- **Two other Vs** that are also important
 - **Validity** of data, correct and accurate to take decision
 - **Volatility** how long is data valid and should be stored

4Vs (2)

The FOUR V's of Big Data

From traffic patterns and music downloads to web history and medical records, data is recorded, stored, and analyzed to enable the technology and services that the world relies on every day. But what exactly is big data, and how can these massive amounts of data be used?

As a leader in the sector, IBM data scientists break big data into four dimensions: **Volume, Velocity, Variety and Veracity**.

Depending on the industry and organization, big data encompasses information from multiple internal and external sources such as transactions, social media, enterprise content, sensors and mobile devices. Companies can leverage data to adapt their products and services to better meet customer needs, optimize operations and infrastructure, and find new sources of revenue.

By 2015, **4.4 MILLION IT JOBS** will be created globally to support big data, with 1.9 million in the United States

As of 2011, the global size of data in healthcare was estimated to be **150 EXABYTES**
[161 BILLION GIGABYTES]

30 BILLION PIECES OF CONTENT are shared on Facebook every month

By 2014, it's anticipated there will be **420 MILLION WEARABLE, WIRELESS HEALTH MONITORS**

**Variety
DIFFERENT
FORMS OF DATA**

4 BILLION+ HOURS OF VIDEO are watched on YouTube each month

400 MILLION TWEETS are sent per day by about 200 million monthly active users

1 IN 3 BUSINESS LEADERS don't trust the information they use to make decisions

Poor data quality costs the US economy around **\$3.1 TRILLION A YEAR**

27% OF RESPONDENTS

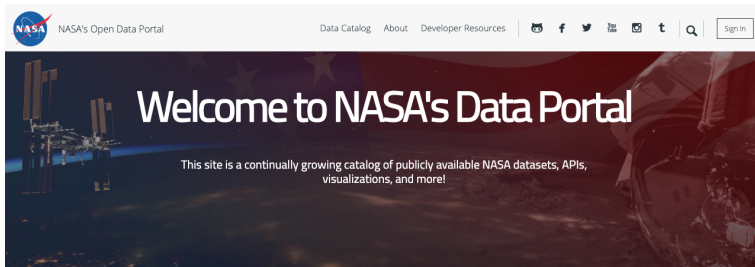

in one survey were unsure of how much of their data was inaccurate

**Veracity
UNCERTAINTY
OF DATA**

Open Data

- Some **open data** should be freely available to everyone
 - To use and to republish as they wish
 - Can be related to linked data, resulting in linked open data
- Sometimes data only accessible under **specific conditions**
 - Open may be a problem with commercially valuable data
 - Access restriction, license, copyright, patent, charge, etc
- A large variety of **sources** do provide open data
 - Government, public or private companies, research centres, etc.*

DoD Digital Strategy Page

The Department of Defense (DoD) maintains a vast amount of information. Information that most folks don't normally associate with Defense. Consider the following:

GPS

The Global Positioning System (GPS) is a space-based satellite navigation system built and maintained by DoD and is freely available to anyone in the world with a GPS receiver. In addition to navigation, uses of GPS include precise timing for financial transactions, search and rescue, communications, farming, recreation and both military and commercial aviation. GPS is operated by the 2nd Space Operations Squadron at Schriever Air Force Base, Colorado.

Open Data Source

The image shows two overlapping web pages. The top page is the NASA's Open Data Portal, featuring the NASA logo, navigation links for Data Catalog, About, and Developer Resources, and social media icons. The bottom page is the EU Open Data Portal, featuring the European Union flag, a search bar, and a list of most viewed datasets.

Open Data Source

The screenshot displays the Data.gov.be website interface. At the top, there are language options (NL, EN, FR, DE) and a link to other official information services (www.belgium.be). The main navigation menu includes HOME, DATA, APPS, NEWS, INFO & FAQ, API/RSS, and CONTACT. The header features the Data.gov.be logo and a search bar. Below the header, a large blue banner contains the text "Data, tools and resources. More than 10,000 datasets." and a search input field. The main content area is a grid of 14 data categories, each represented by an icon and a label: Agriculture and Fisheries, Culture and Sports, Economy and Finance, Education, Energy, Environment, Health, International, Justice, Population, Public Sector, Regional, Science and Technology, and Transport. At the bottom of the page, there are links for GitHub, Terms of Use, and Privacy. A small section at the bottom left shows a search result for "CORDIS - EU research projects under FP7 (2007-2013)" with 23432 views. To the right, there are three icons representing a stethoscope, a microscope, and a scale of justice, with a partially visible text snippet: "world with a GPS receiver. with military and commercial".

Main Actors

facebook

YAHOO!

IBM

Technological Evolution

- First DBMS built around **mainframes**

With the limitations of storage capacities of those time

- Several **technological evolutions** removed those constraints
 - Generalisation of network interconnections
 - Increased available bandwidth over internet
 - Decreased cost of commodity machines

Google FS

- Proprietary **distributed file system** developed by Google
Google File System (GFS) presented in 2003
- Redundant and resilient storage on a **cluster of machines**
Average and “disposable” power (commodity hardware)
- FGS has several nice **characteristics**
 - Designed for machine-machine interactions
 - Executed in the user space, not in OS kernel space
 - Manage files of several gigabytes
 - Automatic replication of data by chunkservers

MapReduce

- **Programming paradigm** and associated implementation
 - Processing and generation of large amounts of data
 - Parallel algorithm distributed on a cluster
- Implementation based on **two functions**
 - Map performs an operation on a list (sort, filter...)
 - Reduce groups data into one single result (sum, max...)

Apache Hadoop

- **Hadoop** open source implementation of MapReduce in Java

By Doug Cutting, named after his son's toy elephant

- **Hadoop Distributed FileSystem** (HDFS)

Inspired by the overview publication on GFS

- Framework used by **many companies**
 - Supported by Microsoft (on Windows Azure and Server)
 - Yahoo! cluster with 4000 machines, soon 10000 with v2.0
 - Facebook announces installation of HDFS with 100 petabytes

BigTable

- GFS-based **data management** system

Proprietary solution again developed by Google

- Data **consistency** management and **distribution** on GFS

Just working like a gigantic distributed hash table

- Several open source implementation **HBase** (Apache)

For example used by eBay, Yahoo! and Twitter

Dynamo

- Distributed and proprietary **key-value pairs** storage (Amazon)
Implemented by Amazon in Simple Storage Service (S3)
- **Four key principles** of Dynamo storage system
 - Incremental scalability with no influence on operator/system
 - Symmetry with all the nodes being equal
 - Complete decentralisation with no central role
 - Heterogeneity by sharing work according to resources
- Creation of several **NoSQL engines** based on Dynamo
Cassandra, Riak, Voldemort project (LinkedIn)...

Data Model

Impedance mismatch (1)

- Object-relational **impedance mismatch** with SQL
 - Moving from relational to object is done with an impedance*
- **Difference** between relational model and memory structure
 - Relations and tuples versus complex data structures*
- Appearance of **object oriented** programming languages
 - Object-Relational Mapping (ORM) such as Hibernate...*

Impedance mismatch (2)

```
1 class Address:
2     def __init__(self, street, number, zipcode, city):
3         self.__address = (street, number, zipcode, city)
4
5     def __str__(self):
6         return '{} , {} \n {} {}'.format(*self.__address)
7
8 ecam = Address("Promenade de l'Alma", 50,
9              1200, "Woluwé-Saint-Lambert")
10 wolubilis = Address("Cours Paul-Henri Spaak", 1,
11                   1200, "Woluwé-Saint-Lambert")
```

Address

Id	Street	Number	CityID
1	Promenade de l'Alma	50	1
2	Cours Paul-Henri Spaak	1	1

City

Id	Zipcode	Name
1	1200	Woluwé-Saint-Lambert

Integration vs Application (1)

- Coordination of several applications **around data**

Sharing data in a single common database

- **Difficult to change** the structure of the database

Non-trivial to ensure data integrity

Integration vs Application (2)

- Access to the database by **a single application**

Provides an access interface to other applications

- Web services deployment and **services oriented architecture**

Greater format flexibility for exchanged data

Data Model (1)

- **Model** with which data are perceived and manipulated

Different from the disk storage model

- **Relational model** consists in tables with rows

Columns with values that can reference other rows

- Moving to a model representing a collection of **aggregates**

Unit of information processed, stored and exchanged atomically

Data Model (2)

- Four main **data models** in the NoSQL world

Detailed analysis of one example for each model

- No single and unambiguous **classification**

Some databases cover several models

Data Model	Database examples
Key-Value	BerkeleyDB, Memcached, Redis , Riak...
Document	CouchDB, MongoDB , OrientDB...
Column	Amazon Simple DB, Cassandra , HBase...
Graph	FlockDB, HyperGraphDB, Neo4j , OrientDB...

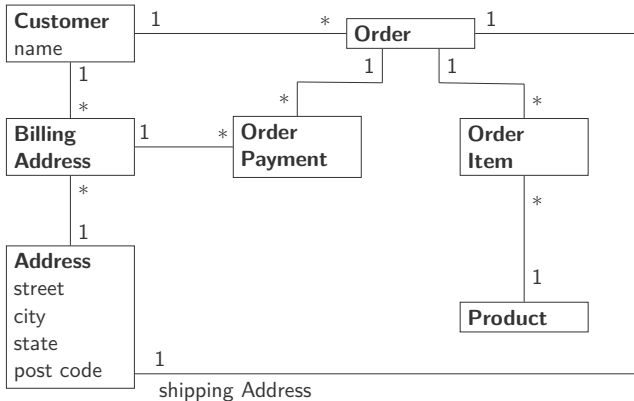

Aggregate

- Operation on complex and structured **data units**
To overcome the limitations of the relational model tuples
- Possible to **nest** lists and other structures in aggregate
Different “objects” handled as units
- Aggregate is the unit to handle and manage **concurrency**
Facilitating the distribution of data on clusters

Relation vs Aggregate (1)

- Fully **normalised** model without any duplicate data

May required a lot of entities and associations

Relation vs Aggregate (2)

Customer

Id	Name
1	Martin

Order

Id	CustomerId	ShippingAddressId
99	1	77

Product

Id	Name
27	NoSQL Distilled

BillingAddress

Id	CustomerId	AddressId
55	1	77

OrderItem

Id	OrderId	ProductId	Price
100	99	27	32.45

Address

Id	City
77	Chicago

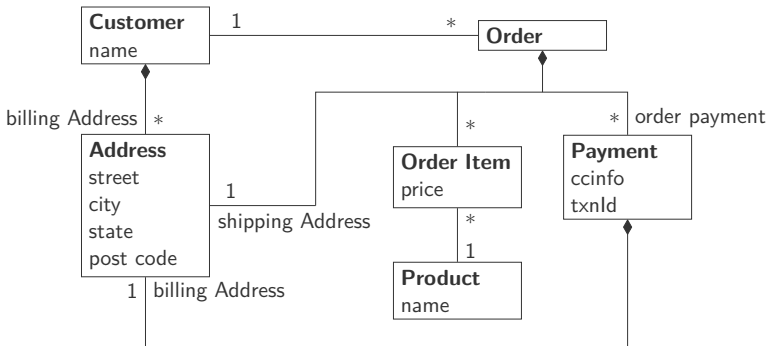

OrderPayment

Id	OrderId	CardNumber	BillingAddressId	txnId
33	99	1000-1000	55	abelif879rft

Relation vs Aggregate (3)

- Model consisting of **two main aggregates**

Customer and Order composed of "sub-aggregates"

Relation vs Aggregate (4)

```
1 # Customer
2 {
3   "id": 1,
4   "name": "Martin",
5   "billingAddress": [{"city": "Chicago"}]
6 }
7
8 # Order
9 {
10  "id": 99,
11  "customerId": 1,
12  "orderItems": [{
13    "productId": 27,
14    "price": 32.45,
15    "productName": "NoSQL Distilled"
16  }],
17  "shippingAddress": [{"city": "Chicago"}],
18  "orderPayment": [{
19    "ccinfo": "1000-1000",
20    "txnId": "abelif879rft",
21    "billingAddress": {"city": "Chicago"}
22  }]
23 }
```

Key-Value

- Aggregate stored in **key-value** form

The key acts as the unique identifier of each aggregate

- An aggregate is retrieved **thanks to its key**

Key-value stores work as lookup tables

Document

- Aggregate stored in **document** form

Each document is uniquely identified by an ID

- Retrieving the whole document or **part of a document**

From queries on the fields of the aggregate

- Creation of an **index** based on the content of documents

To speed up search operations in the database

Column

- **Columns** are stored on the disk instead of rows

Column storage can be seen as a two-level map

- Key-value structure with **row identifier** as key

The second level contains information about the columns

Graph

- Possible to have **relations** between aggregates

With automatic update possibility

- Useful for small records with **a lot of links**

Set of nodes connected by edges

- Social networks, preferences, eligibility rules...

“What are all the things Theo and Yannis both like?”

NoSQL Characteristics

Schema-Less Database

- NoSQL databases do not have **data schema**

Unlike the rigid structure imposed by the relational model

- **Unrestricted addition** of data of any type

Such as key, document, column, edge and properties

- Possible to store **non-uniform data**

Which eliminates the need to have NULL values

Implicit Schema

- **Assumptions** about the data structure in the code

The database remains ignorant, it is the application that checks

- Danger if **multiple applications** on the same database

They have to agree on the data schema

- **Data migration** must always be done carefully

Should it be with the relational or NoSQL models

Developer Centered

- **Developer** centered development methodology
 - Design and implementation of the application architecture
 - Data modelling
- Two different approaches **RDBMS vs NoSQL**
 - Relational data models are defined thanks to theory
 - Application queries and configuration to be supported

NoSQL Architecture

- Building database on **relational** with DBMS
 - Description of data structures and storage
 - Data recovery process and reliability
 - Data in tables (record and column) and not repeated
 - Importance of primary keys
- Data management much **more flexible** with NoSQL
 - Distribution across multiple servers, platforms, processors
 - Gradual evolution of the (implicit) data schema

Data Operation and Relation

- **CRUD** standard operations with RDBMS

Create, Read, Update, Delete

- Much more **diverse and varied** operations in NoSQL

- Large number of additions and updates

- Operations on other entities than rows of tables

- NoSQL not adapted to data with **a lot of relations**

RDBMS have one-to-one, one-to-many and many-to-many
